Conditional Execution

Chapter 3

Python for Everybody www.py4e.com

x = 5Yes x < 10? print('Smaller') No Yes x > 20? No print('Bigger') print('Finis')

Conditional Steps

```
Program:

x = 5
if x < 10:
    print('Smaller')
if x > 20:
    print('Bigger')

print('Finis')
Output:

Smaller
Finis
```

Comparison Operators

- Boolean expressions ask a question and produce a Yes or No result which we use to control program flow
- Boolean expressions using comparison operators evaluate to True / False or Yes / No
- Comparison operators look at variables but do not change the variables

Python	Meaning
<	Less than
<=	Less than or Equal to
==	Equal to
>=	Greater than or Equal to
>	Greater than
!=	Not equal

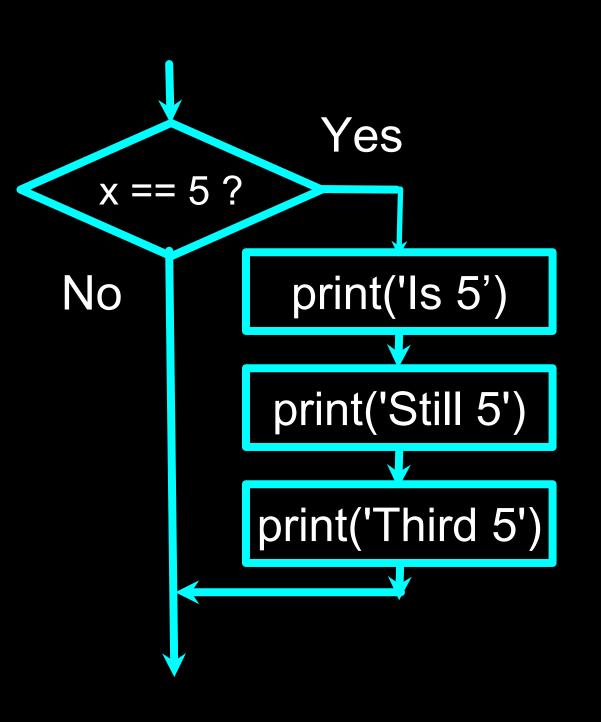

Remember: "=" is used for assignment.

Comparison Operators

```
x = 5
if x == 5 :
                                           Equals 5
   print('Equals 5')
if x > 4:
                                           Greater than 4
   print('Greater than 4')
if x >= 5:
                                           Greater than or Equals 5
    print('Greater than or Equals 5')
if x < 6 : print('Less than 6')
                                           Less than 6
if x <= 5:
                                           Less than or Equals 5
    print('Less than or Equals 5')
if x != 6:
                                           Not equal 6
    print('Not equal 6')
```

One-Way Decisions

```
x = 5
                              Before 5
print('Before 5')
    x == 5:
    print('Is 5')
                              ls 5
    print('Is Still 5')
                              Is Still 5
    print('Third 5')
                              Third 5
print('Afterwards 5')
                              Afterwards 5
print('Before 6')
                              Before 6
if x == 6 :
    print('Is 6')
    print('Is Still 6')
    print('Third 6')
print('Afterwards 6')
```

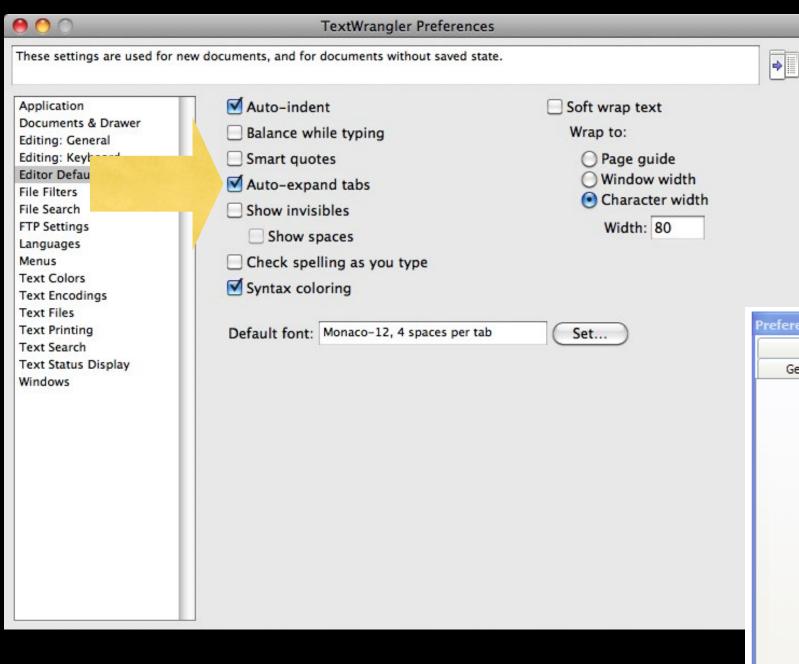

Afterwards 6

Indentation Matters

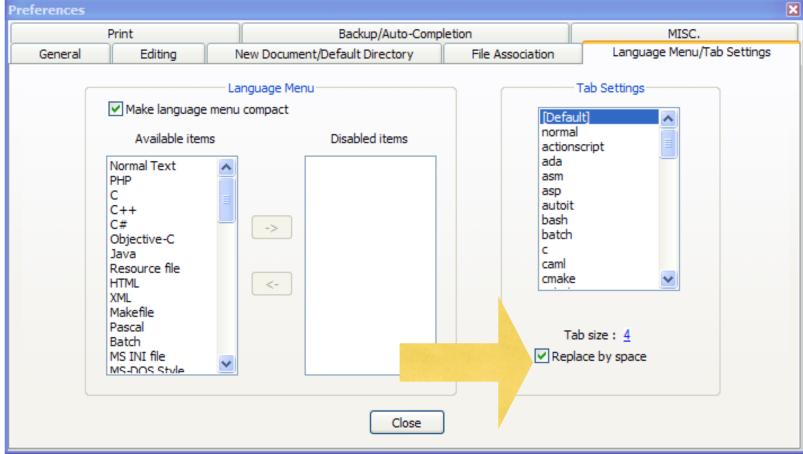

- Increase indent indent after an if statement or for statement (after:)
- Maintain indent to indicate the scope of the block (which lines are affected by the if/for)
- Reduce indent back to the level of the if statement or for statement to indicate the end of the block
- Blank lines are ignored they do not affect indentation
- Comments on a line by themselves are ignored with regard to indentation

Warning: Turn Off Tabs!!

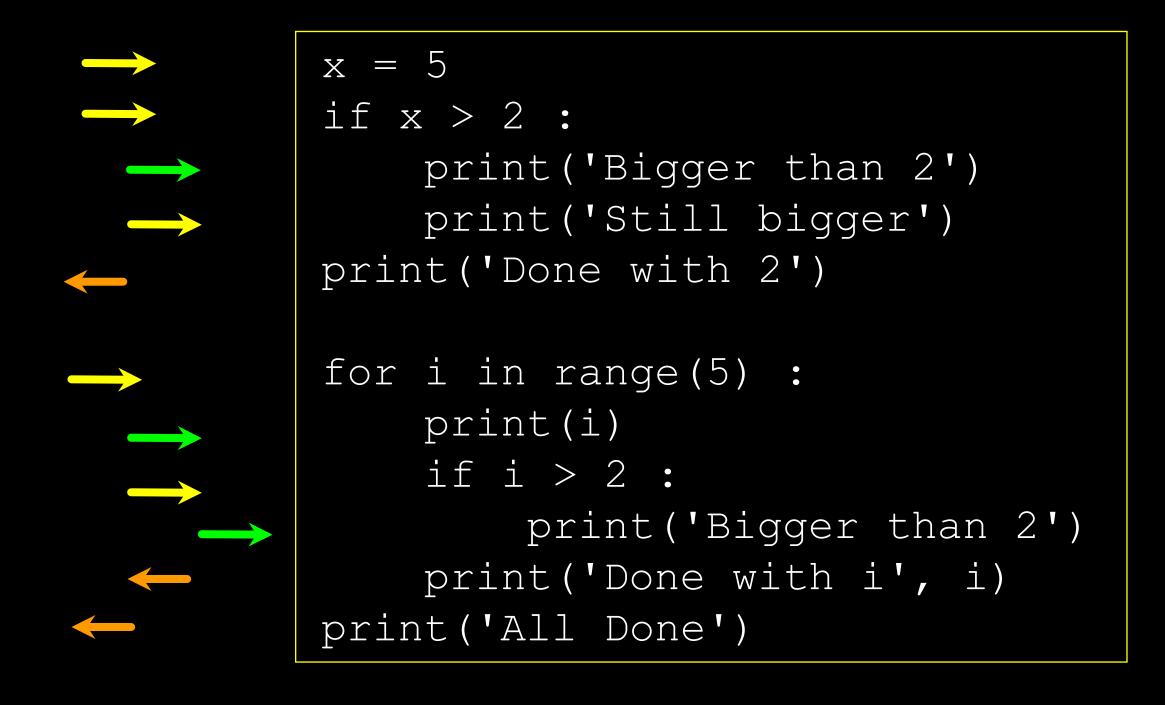

- Atom automatically uses spaces for files with ".py" extension (nice!)
- Most text editors can turn tabs into spaces make sure to enable this feature
 - NotePad++: Settings -> Preferences -> Language Menu/Tab Settings
 - TextWrangler: TextWrangler -> Preferences -> Editor Defaults
- Python cares a *lot* about how far a line is indented. If you mix tabs and spaces, you may get "indentation errors" even if everything looks fine

This will save you much unnecessary pain.

increase / maintain after if or for decrease to indicate end of block

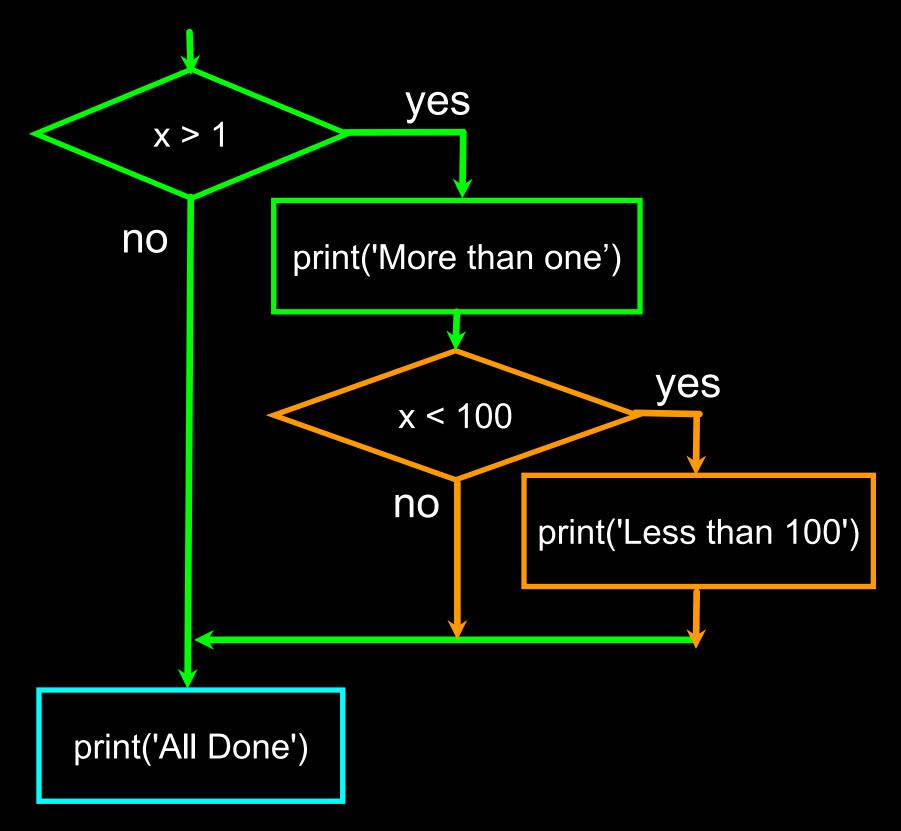

Think About begin/end Blocks

```
x = 5
if x > 2:
    print('Bigger than 2')
    print('Still bigger')
print('Done with 2')
for i in range(5) :
    print(i)
    if i > 2 :
        print('Bigger than 2')
    print('Done with i', i)
print('All Done')
```

Nested Decisions

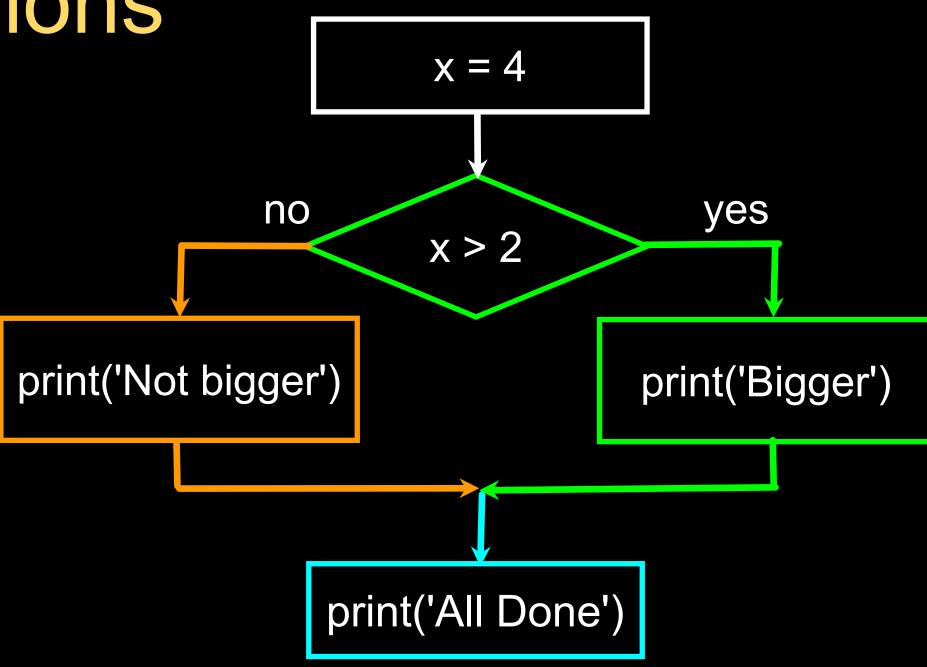

```
x = 42
if x > 1 :
    print('More than one')
    if x < 100 :
        print('Less than 100')
print('All done')</pre>
```

Two-way Decisions

 Sometimes we want to do one thing if a logical expression is true and something else if the expression is false

 It is like a fork in the road - we must choose one or the other path but not both

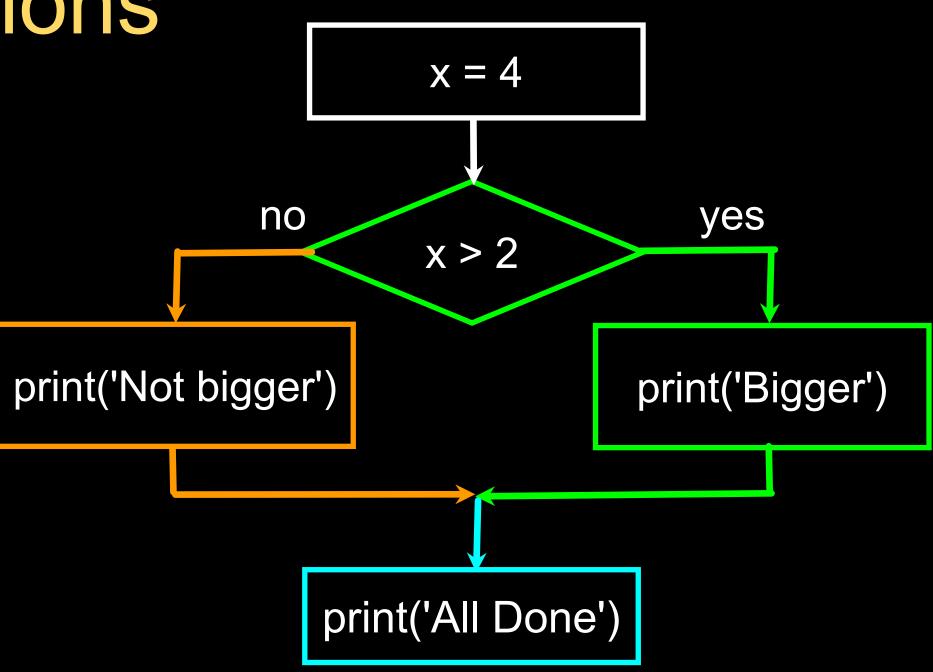

Two-way Decisions with else:

```
x = 4

if x > 2:
    print('Bigger')
else:
    print('Smaller')

print('All done')
```

Visualize Blocks

```
x = 4

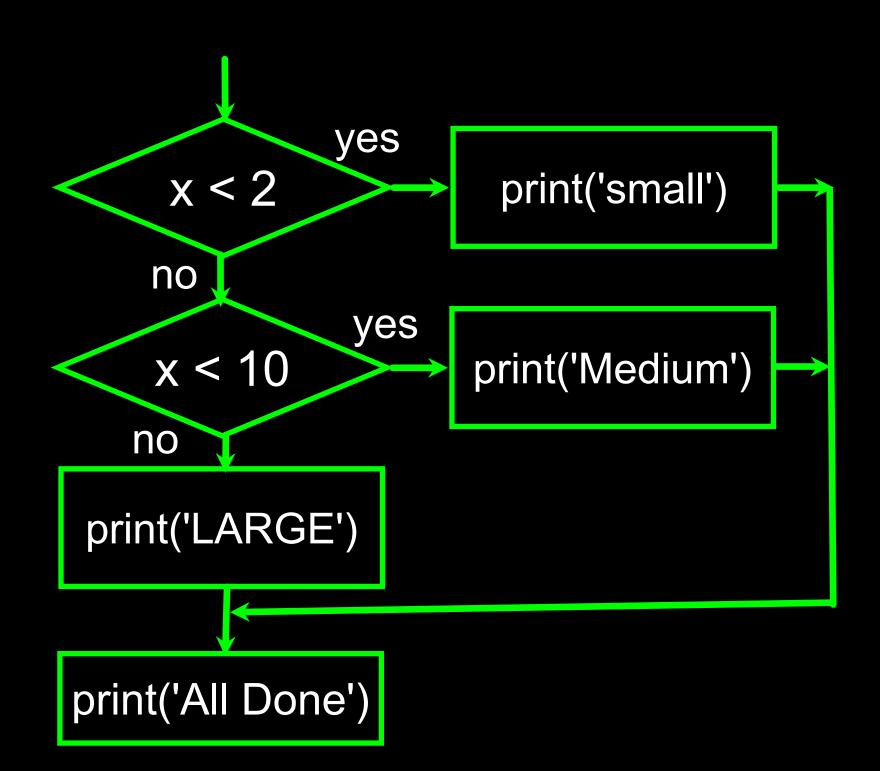

if x > 2:
    print('Bigger')
else:
    print('Smaller')

print('All done')
```

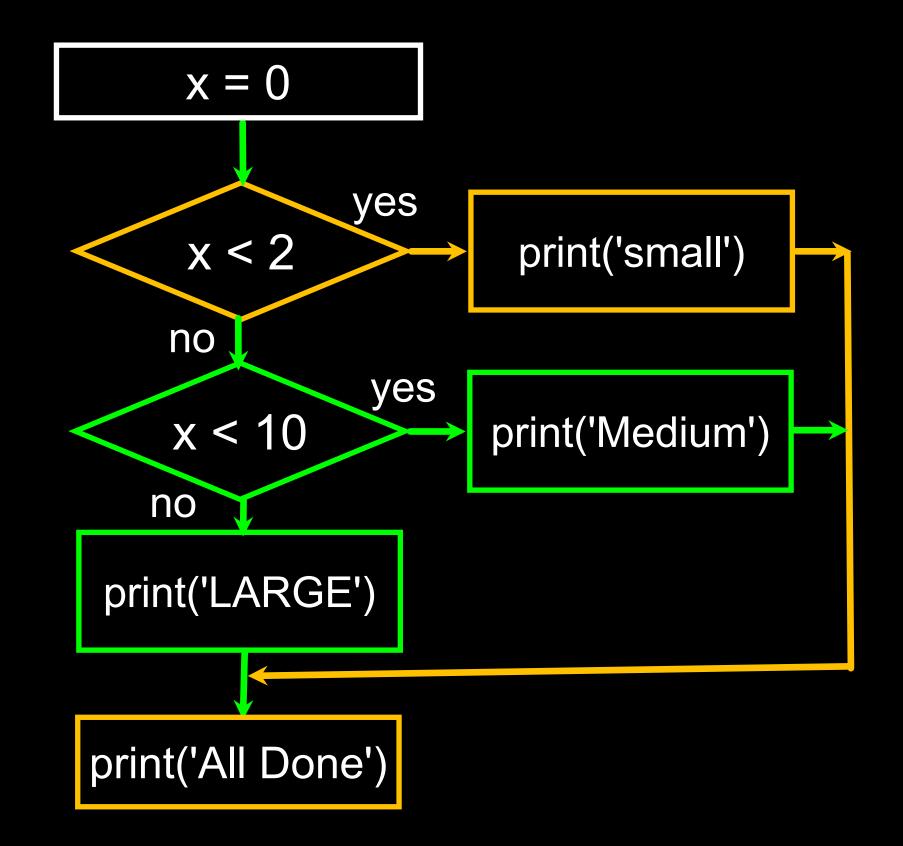

```
x = 4
              no
                                       yes
                       x > 2
print('Not bigger')
                                    print('Bigger')
                 print('All Done')
```

More Conditional Structures...

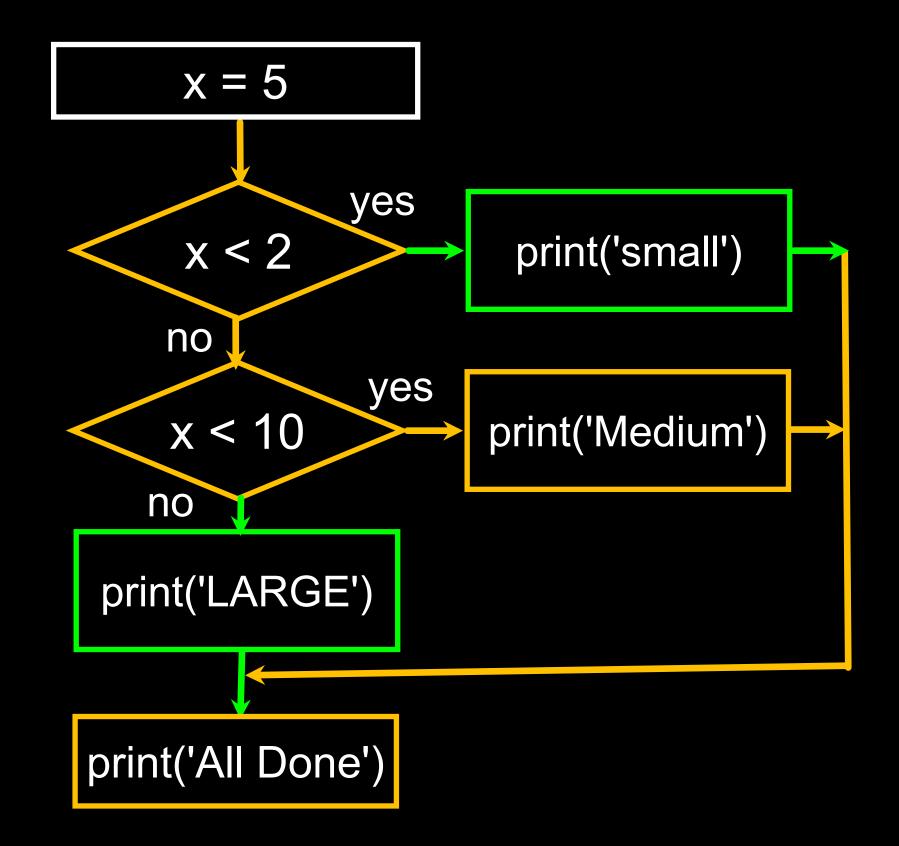

```
if x < 2:
    print('small')
elif x < 10:
    print('Medium')
else:
    print('LARGE')
print('All done')</pre>
```

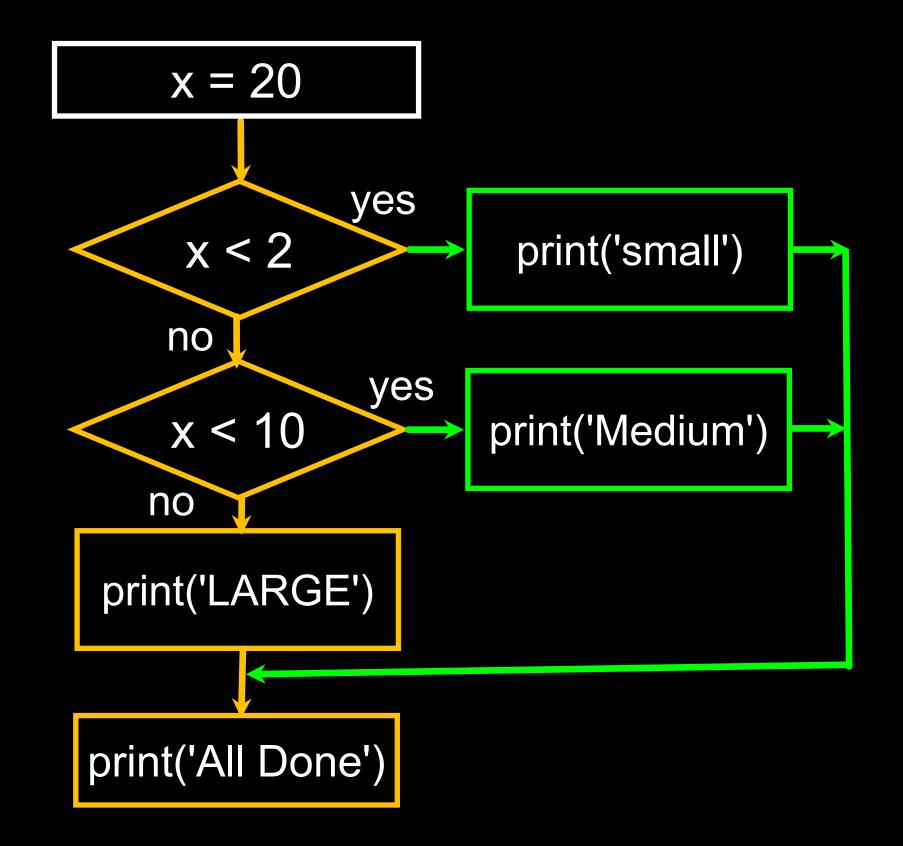

```
x = 0
if x < 2:
    print('small')
elif x < 10:
    print('Medium')
else:
    print('LARGE')
print('All done')</pre>
```

```
x = 5
if x < 2 :
    print('small')
elif x < 10 :
    print('Medium')
else :
    print('LARGE')
print('All done')</pre>
```

```
x = 20
if x < 2:
    print('small')
elif x < 10:
    print('Medium')
else:
    print('LARGE')
print('All done')</pre>
```

```
# No Else
x = 5
if x < 2:
    print('Small')
elif x < 10:
    print('Medium')

print('All done')</pre>
```

```
if x < 2:
    print('Small')
elif x < 10:
    print('Medium')
elif x < 20:
    print('Big')
elif x < 40:
    print('Large')
elif x < 100:
    print('Huge')
else :
    print('Ginormous')
```

Multi-way Puzzles

Which will never print regardless of the value for x?

```
if x < 2 :
    print('Below 2')
elif x >= 2 :
    print('Two or more')
else :
    print('Something else')
```

```
if x < 2 :
    print('Below 2')
elif x < 20 :
    print('Below 20')
elif x < 10 :
    print('Below 10')
else :
    print('Something else')</pre>
```

The try / except Structure

- You surround a dangerous section of code with try and except
- If the code in the try works the except is skipped
- If the code in the try fails it jumps to the except section

\$ cat notry.py astr = 'Hello Bob' istr = int(astr) print('First', istr) astr = '123' istr = int(astr) print('Second', istr)

\$ python3 notry.py

Traceback (most recent call last):
File "notry.py", line 2, in <module>
istr = int(astr)ValueError: invalid literal
for int() with base 10: 'Hello Bob'

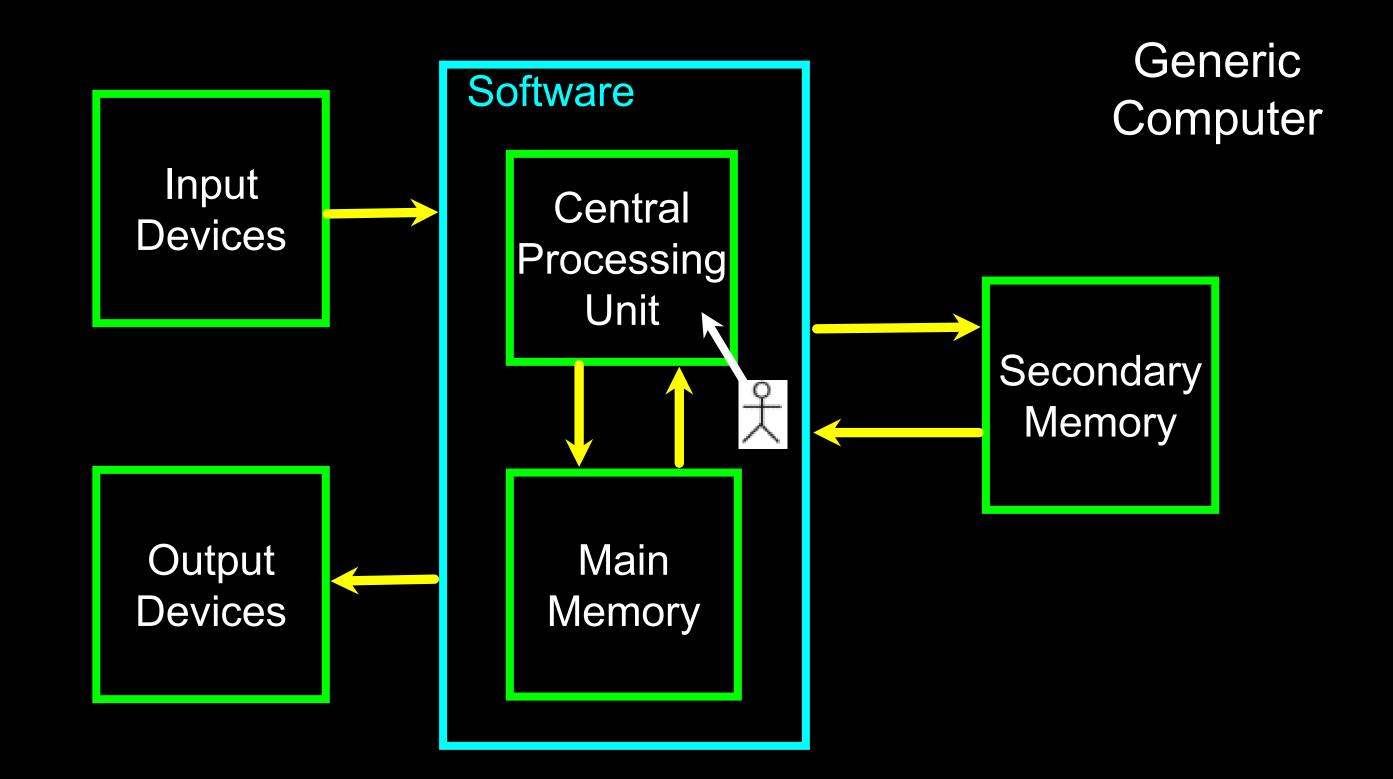

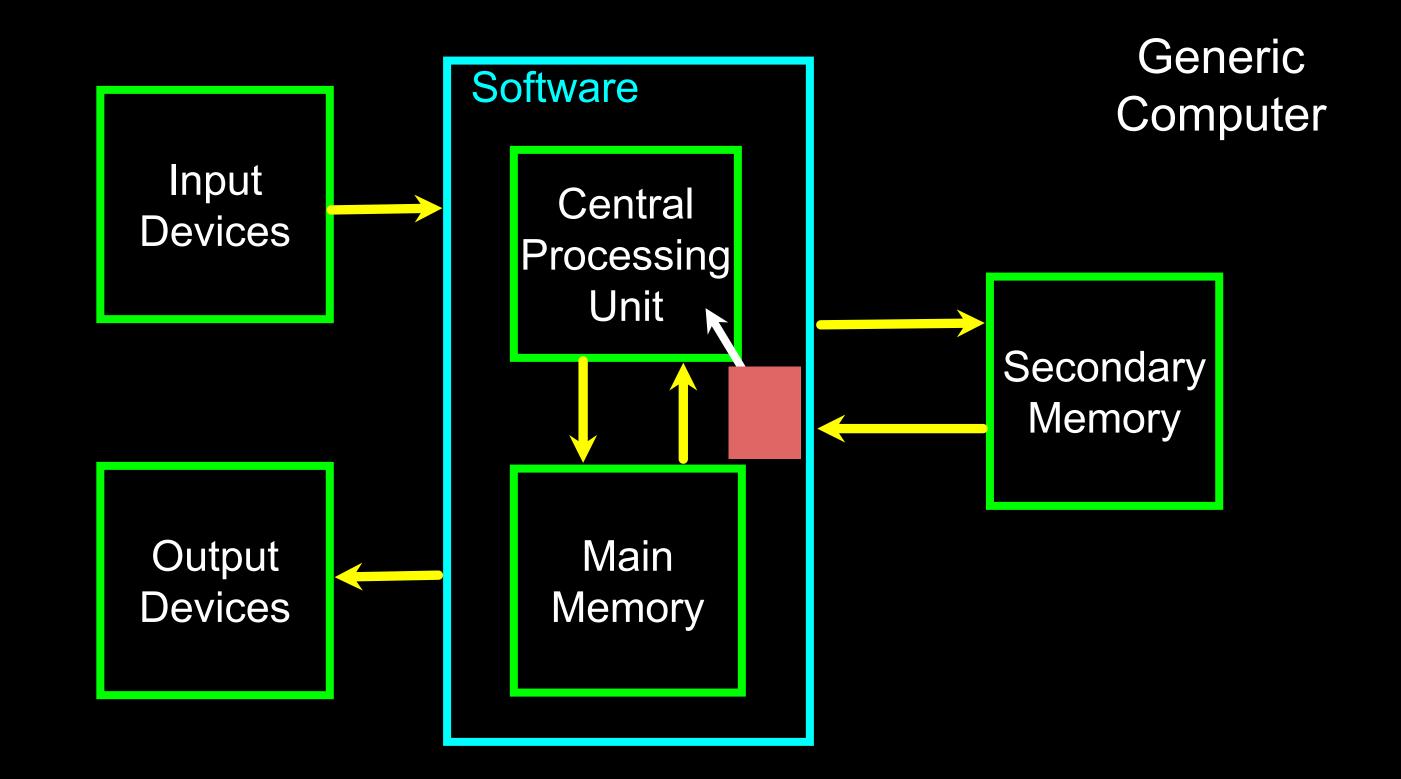

```
The
program
 stops
             cat notry.py
 here
           astr = 'Hello Bob'
      \rightarrow istr = int(astr)
```

\$ python3 notry.py

Traceback (most recent call last):
File "notry.py", line 2, in <module>
istr = int(astr)ValueError: invalid literal
for int() with base 10: 'Hello Bob'

```
astr = 'Hello Bob'
try:
   istr = int(astr)
except:
    istr = -1
print('First', istr)
astr = '123'
try:
   istr = int(astr)
except:
    istr = -1
print('Second', istr)
```

When the first conversion fails - it just drops into the except: clause and the program continues.

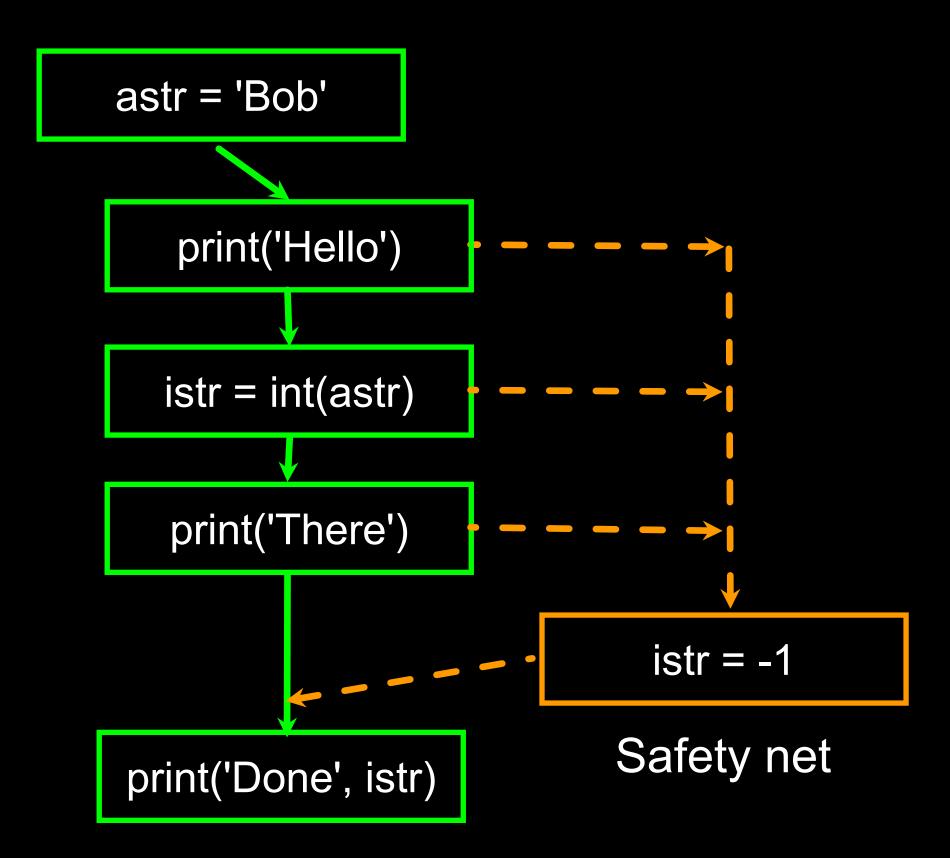

```
$ python tryexcept.py
First -1
Second 123
```

When the second conversion succeeds - it just skips the except: clause and the program continues.

try / except

```
astr = 'Bob'
try:
    print('Hello')
    istr = int(astr)
    print('There')
except:
    istr = -1

print('Done', istr)
```

Sample try / except

```
rawstr = input('Enter a number:')
try:
    ival = int(rawstr)
except:
    ival = -1

if ival > 0 :
    print('Nice work')
else:
    print('Not a number')
```

```
$ python3 trynum.py
Enter a number:42
Nice work
$ python3 trynum.py
Enter a number:forty-two
Not a number
$
```

Summary

- Comparison operators== <= >= > < !=
- Indentation
- One-way Decisions
- Two-way decisions:
 if: and else:

- Nested Decisions
- Multi-way decisions using elif
- try / except to compensate for errors

Exercise

Rewrite your pay computation to give the employee 1.5 times the hourly rate for hours worked above 40 hours.

```
Enter Hours: 45
```

Enter Rate: 10

Pay: 475.0

475 = 40 * 10 + 5 * 15

Exercise

Rewrite your pay program using try and except so that your program handles non-numeric input gracefully.

```
Enter Hours: 20
Enter Rate: nine
Error, please enter numeric input
Enter Hours: forty
Error, please enter numeric input
```
